

# High Temperature in the Hot Aisle of the Computer Room

## Overview

Ventilation is more than just moving air in and out; it involves managing airflow, adjusting the room layout, and choosing the right cooling systems. Good airflow and effective cooling help prevent hot spots and control temperature, protecting hardware and extending its life. Traditional open aisle data centres use perimeter PAC (precision air conditioning) or CRAC (computer room air conditioning) units to channel cold air up through a raised floor void via grilles positioned in front of the IT cabinets. This has significant disadvantages as there is no separation. Hot aisle containment (HAC) is a proven cooling management strategy that physically isolates hot exhaust air from IT equipment using strategic barriers including doors, walls, and ceiling panels. They aren't new, but when used right, they turn chaos into control.
